

GALAHAD

SORT

PACKAGE SPECIFICATION

GALAHAD Optimization Library version 2.1

1 SUMMARY

GALAHAD_SORT is a suite of Fortran procedures for sorting and permuting. It includes two algorithms (heapsort and quicksort) to sort integer and/or real vectors, another to reorder a sparse matrix from co-ordinate to row format, and a further three tools for in-place permutation and permutation inversion.

ATTRIBUTES — Versions: GALAHAD_SORT_single, GALAHAD_SORT_double. **Date:** March 2002. **Origin:** N. I. M. Gould, Rutherford Appleton Laboratory, and Ph. L. Toint, University of Namur, Belgium. **Language:** Fortran 95 + TR 15581 or Fortran 2003.

2 HOW TO USE THE PACKAGE

Access to the package requires a USE statement such as

Single precision version

```
USE GALAHAD_SORT_single
```

Double precision version

```
USE GALAHAD_SORT_double
```

2.1 Argument lists and calling sequences

There are seven procedures that may be called by the user.

1. The subroutine `SORT_inplace_invert` is used to invert a permutation vector without resorting to extra storage.
2. The subroutine `SORT_inplace_permute` is used to apply a given permutation to an integer vector and, optionally, to a real vector, without resorting to extra storage.
3. The subroutine `SORT_inverse_permute` is used to apply the inverse of a given permutation to an integer vector and, optionally, to a real vector, without resorting to extra storage.
4. The subroutine `SORT_reorder_by_rows` is used to reorder a sparse matrix from arbitrary co-ordinate order to row order, that is so that the entries for row i appear directly before those for row $i + 1$.
5. The subroutine `SORT_quicksort` is used to sort a given integer/real vector **in ascending order**, optionally applying the same permutation to integer and/or to a real vector(s). It uses the “quicksort” algorithm (see Section 4).
6. The subroutine `SORT_heapsort_build` is used to initialize a procedure to sort a vector of real numbers using the “heapsort” algorithm (see Section 4).
7. The subroutine `SORT_heapsort_smallest` is used to find, possibly repeatedly, the smallest component of a real vector to which `SORT_heapsort_build` has been previously applied (see Section 4). Successive application of this subroutine therefore results in sorting the initial vector **in ascending order**.

All use is subject to licence. See <http://galahad.rl.ac.uk/galahad-www/cou.html>.
For any commercial application, a separate license must be signed.

Note that the subroutines `SORT_heapsort_build` and `SORT_heapsort_smallest` are particularly appropriate if it is not known in advance how many successive smallest components of the vector will be required as the heapsort method is able to calculate the $k + 1$ -st smallest component efficiently once it has determined the first k smallest components. If a complete sort is required, the Quicksort algorithm, `SORT_quicksort` may be preferred. Both methods are guaranteed to sort all n numbers in $O(n \log n)$ operations.

We use square brackets [] to indicate OPTIONAL arguments.

2.1.1 In-place inversion of a permutation

A permutation p of size n is a vector of n integers ranging from 1 to n , each integer in this range occurring exactly once. Its inverse is another permutation q , also of size n , such that $q(p(i)) = i$ for all $i = 1, \dots, n$. Inverting a given permutation without resorting to extra storage is done as follows:

```
CALL SORT_inplace_invert ( n, p )
```

n is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to n , the size of the permutation to be inverted. **Restriction:** $n > 0$.

p is a rank-one `INTENT(INOUT)` array argument of dimension at least n and type either default `INTEGER` or default `REAL` (double precision in `GALAHAD_SORT_double`), that must be set by the user on input so that its i -th component contains the integer $p(i)$. On exit, the elements of p will have overwritten by those of q , the inverse of p .

2.1.2 Applying a given permutation in place

Applying a given permutation p to a vector x consists in modifying the vector x such that its i -th component appears (after applying the permutation) in component $p(i)$. This is done without resorting to extra storage as follows:

```
CALL SORT_inplace_permute ( n, p [, x] [, ix] [, iy] )
```

n is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to n , the size of the permutation to be applied. **Restriction:** $n > 0$.

p is a rank-one `INTENT(INOUT)` array argument of dimension at least n and type either default `INTEGER` or default `REAL` (double precision in `GALAHAD_SORT_double`), that must be set by the user on input so that its i -th component contains the integer $p(i)$, that is the i -th component of the permutation one wishes to apply. It is unchanged on exit.

x is an optional rank-one `INTENT(INOUT)` array argument of dimension at least n and type `REAL` (double precision in `GALAHAD_SORT_double`), whose n first components must be set by the user. If x is present, the component $x(i)$ will have been replaced by $x(p(i))$ on exit.

ix is an optional rank-one `INTENT(INOUT)` array argument of dimension at least n and type `INTEGER`, whose n first components must be set by the user. If ix is present, the component $ix(i)$ will have been replaced by $ix(p(i))$ on exit.

iy is an optional rank-one `INTENT(INOUT)` array argument of dimension at least n and type `INTEGER`, whose n first components must be set by the user. If iy is present, the component $iy(i)$ will have been replaced by $iy(p(i))$ on exit.

All use is subject to licence. See <http://galahad.rl.ac.uk/galahad-www/cou.html>.
For any commercial application, a separate license must be signed.

2.1.3 Applying the inverse of a given permutation in place

Applying the inverse of a given permutation p to a vector x consists in modifying the vector x such that its i -th component appears (after applying the procedure) in component $q(i)$, where q is the inverse of p . Equivalently, this can be seen as modifying the vector x such that its $p(i)$ -th component appears (after applying the procedure) in component i . This is done without resorting to extra storage as follows:

```
CALL SORT_inverse_permute ( n, p [, x] [, ix] )
```

n is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to n , the size of the permutation whose inverse is to be applied. **Restriction:** $n > 0$.

p is a rank-one `INTENT(INOUT)` array argument of dimension at least n and type either default `INTEGER` or default `REAL` (double precision in `GALAHAD_SORT_double`), that must be set by the user on input so that its i -th component contains the integer $p(i)$, that is the i -th component of the permutation whose inverse is to be applied. It is unchanged on exit.

x is an optional rank-one `INTENT(INOUT)` array argument of dimension at least n and type `REAL` (double precision in `GALAHAD_SORT_double`), whose n first components must be set by the user. If x is present, the component $x(i)$ will have been replaced by $x(p(i))$ on exit.

ix is an optional rank-one `INTENT(INOUT)` array argument of dimension at least n and type `INTEGER`, whose n first components must be set by the user. If ix is present, the component $ix(i)$ will have been replaced by $ix(p(i))$ on exit.

2.1.4 Reordering a sparse matrix from co-ordinate to row order

The matrix A is reordered from co-ordinate to row order as follows:

```
CALL SORT_reorder_by_rows( nr, nc, nnz, A_row, A_col, la, A_val, A_ptr, lptr,      &
                           IW, liw, error, warning, inform )
```

nr is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to the number of rows in A . **Restriction:** $nr > 0$.

nc is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to the number of columns in A . **Restriction:** $nc > 0$.

nnz is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to the number of nonzeros in A . **Restriction:** $nnz > 0$.

A_row is a rank-one `INTENT(INOUT)` array argument of type default `INTEGER` and length la . On entry, $A_row(k)$, $k = 1, \dots, nnz$ give the row indices of A . On exit, A_row will have been reordered, but $A_row(k)$ will still be the row index corresponding to the entry with column index $A_col(k)$.

A_col is a rank-one `INTENT(INOUT)` array argument of type default `INTEGER` and length la . On entry, $A_col(k)$, $k = 1, \dots, nnz$ give the column indices of A . On exit, A_col will have been reordered so that entries in row i appear directly before those in row $i + 1$ for $i = 1, \dots, nr - 1$.

la is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to the actual dimension of the arrays A_row , A_col and A_val . **Restriction:** $la \geq nnz$.

A_val is a rank-one `INTENT(INOUT)` array argument of type default `REAL` (double precision in `GALAHAD_SORT_double`) of length la . On entry, $A_val(k)$, $k = 1, \dots, nnz$ give the values of A . On exit, A_val will have been reordered so that entries in row i appear directly before those in row $i + 1$ for $i = 1, \dots, nr - 1$ and correspond to those in A_row and A_col .

All use is subject to licence. See <http://galahad.rl.ac.uk/galahad-www/cou.html>.
For any commercial application, a separate license must be signed.

`A_ptr` is a rank-one `INTENT(OUT)` array argument of type default `INTEGER` and length `lptr`. On exit, `A_ptr(i), i = 1, ..., nr` give the starting addresses for the entries in `A_row/A_col/A_val` in row i , while `A_ptr(nr+1)` gives the index of the first non-occupied component of **A**.

`lptr` is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to the actual dimension of `A_ptr`. **Restriction:** $lptr \geq nr + 1$.

`IW` is a rank-one `INTENT(OUT)` array argument of type default `INTEGER` and length `liw` that is used for workspace.

`liw` is a scalar `INTENT(IN)` argument of type default `INTEGER`, that gives the actual dimension of `IW`. **Restriction:** $liw \geq \text{MAX}(nr, nc) + 1$.

`error` is a scalar `INTENT(IN)` argument of type default `INTEGER`, that holds the stream number for error messages. Error messages will only occur if `error` > 0 .

`warning` is a scalar `INTENT(IN)` argument of type default `INTEGER`, that holds the stream number for warning messages. Warning messages will only occur if `warning` > 0 .

`inform` is a scalar `INTENT(OUT)` argument of type default `INTEGER`. A successful call to `SORT_reorder_by_rows` is indicated when `inform` has the value 0 on exit. For other return values of `inform`, see Section 2.2.

2.1.5 Quicksort

The vector x is sorted in ascending order as follows:

```
CALL SORT_quicksort ( n, x, inform [, ix] [, rx] )
```

`n` is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to n , the number of entries of x that are to be sorted. **Restriction:** $n > 0$ and $n < 2^{32}$.

`x` is a rank-one `INTENT(INOUT)` array argument of dimension at least n and type either default `INTEGER` or default `REAL` (double precision in `GALAHAD_SORT_double`), whose first n components must be set by the user on input. On successful return, these components will have been sorted to ascending order.

`inform` is a scalar `INTENT(OUT)` argument of type default `INTEGER`. A successful call to `SORT_quicksort` is indicated when `inform` has the value 0 on exit. For other return values of `inform`, see Section 2.2.

`ix` is an optional rank-one `INTENT(INOUT)` array argument of dimension at least n and type default `INTEGER`. If `ix` is present, exactly the same permutation is applied to the components of `ix` as to the components of `x`. For example, the inverse permutation will be provided if `ix(i)` is set to i , for $i = 1, \dots, n$ on entry.

`rx` is an optional rank-one `INTENT(INOUT)` array argument of dimension at least n and type default `REAL` (double precision in `GALAHAD_SORT_double`). If `rx` is present, exactly the same permutation is applied to the components of `rx` as to the components of `x`.

2.1.6 Heapsort

Building the initial heap The initial heap is constructed as follows:

```
CALL SORT_heapsort_build ( n, x, inform [, ix] )
```

`n` is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to n , the number of entries of **A** that are to be (partially) sorted. **Restriction:** $n > 0$.

`x` is a rank-one `INTENT(INOUT)` array argument of dimension at least n and type either default `INTEGER` or default `REAL` (double precision in `GALAHAD_SORT_double`), whose first n components must be set by the user on input. On successful return, the elements of `x` will have been permuted so that they form a heap.

All use is subject to licence. See <http://galahad.rl.ac.uk/galahad-www/cou.html>.
For any commercial application, a separate license must be signed.

`inform` is a scalar `INTENT(OUT)` argument of type default `INTEGER`. A successful call to `SORT_heapsort_build` is indicated when `inform` has the value 0 on exit. For other return values of `inform`, see Section 2.2.

`ix` is an optional rank-one `INTENT(INOUT)` array argument of dimension at least `n` and type default `INTEGER`. If `ix` is present, exactly the same permutation is applied to the components of `ix` as to the components of `x`. For example, the inverse permutation will be provided if `ix(i)` is set to `i`, for $i = 1, \dots, n$ on entry.

Finding the smallest entry in the current heap To find the smallest entry in a given heap, to place this entry at the end of the list of entries in the heap and to form a new heap with the remaining entries:

```
CALL SORT_heapsort_smallest ( m, x, inform [, ix ] )
```

`m` is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set by the user to `m`, the number of entries of `A` that lie on the heap on entry. **Restriction:** $m > 0$.

`x` is a rank-one `INTENT(INOUT)` array argument of dimension at least `m` and type either default `INTEGER` or default `REAL` (double precision in `GALAHAD_SORT_double`) whose first `m` components must be set by the user on input so that they form a heap. In practice, this normally means that they have been placed on a heap by a previous call to `SORT_heapsort_build` or `SORT_heapsort_smallest`. On output, the smallest of the first `m` components of `x` will have been moved to position `x(m)` and the remaining components will now occupy locations 1, 2, ..., `m-1` of `x` and will again form a heap.

`inform` is a scalar `INTENT(OUT)` argument of type default `INTEGER`. A successful call to `SORT_heapsort_smallest` is indicated when `inform` has the value 0 on exit. For other return values of `inform`, see Section 2.2.

`ix` is an optional rank-one `INTENT(INOUT)` array argument of dimension at least `m` and type default `INTEGER`. If `ix` is present, exactly the same permutation is applied to the components of `ix` as to the components of `x`.

Finding the k smallest components of a set of n elements To find the k smallest components of a set, $\{x_1, x_2, \dots, x_n\}$, of n elements, the user should firstly call `SORT_heapsort_build` with $n = n$ and x_1 to x_n stored in `x(1)` to `x(n)`. This places the components of `x` on a heap. This should then be followed by k calls of `SORT_heapsort_smallest`, with $m = n - i + 1$ for $i = 1, \dots, k$. The required k smallest values, in increasing order, will now occupy positions $n - i + 1$ of `x` for $i = 1, \dots, k$.

2.2 Warning and error messages

A positive value of `inform` on exit from `SORT_reorder_by_rows`, `SORT_quicksort`, `SORT_heapsort_build` or `SORT_heapsort_smallest` indicates that an input error has occurred. The other arguments will not have been altered. The only possible values are:

1. One or more of the restrictions $nr > 0$, $nc > 0$, $nnz > 0$ (`SORT_reorder_by_rows`), $n > 0$ (`SORT_quicksort`, `SORT_heapsort_build`) or $m > 0$ (`SORT_heapsort_smallest`) has been violated.
2. One of the restrictions $la \geq nnz$ (`SORT_reorder_by_rows`) or $n < 2^{32}$ (`SORT_quicksort`) has been violated.
3. The restriction $liw \geq \max(nr, nc) + 1$ (`SORT_reorder_by_rows`) has been violated.
4. The restriction $lptr \geq nr + 1$ (`SORT_reorder_by_rows`) has been violated.
5. All of the entries input in `A_row` and `A_col` are out of range.

A negative value of `inform` on exit from `SORT_reorder_by_rows` indicates that `A` has been successfully reordered, but that a warning condition has occurred. The only possible values are:

- 1. There were duplicate input entries, which have been summed.

All use is subject to licence. See <http://galahad.rl.ac.uk/galahad-www/cou.html>.
For any commercial application, a separate license must be signed.

- 2. There were input row entries out of range, which have been ignored.
- 3. There were input column entries out of range, which have been ignored.

3 GENERAL INFORMATION

Use of common: None.

Workspace: None.

Other routines called directly: None.

Other modules used directly: None.

Input/output: None.

Restrictions: $nr > 0$, $nc > 0$, $nnz > 0$, $la \geq nnz$, $liw \geq \max(nr, nc) + 1$, $lptr \geq nr + 1$, (SORT_reorder_by_rows), $n > 0$ (SORT_quicksort and SORT_heapsort_build), $m > 0$ (SORT_heapsort_smallest) and $n < 2^{32}$ (SORT_quicksort)

Portability: ISO Fortran 95 + TR 15581 or Fortran 2003. The package is thread-safe.

4 METHOD

4.1 Quicksort

The quicksort method is due to C. A. R. Hoare (Computer Journal, **5** (1962), 10-15).

The idea is to take one component of the vector to sort, say x_1 , and to move it to the final position it should occupy in the sorted vector, say position p . While determining this final position, the other components are also rearranged so that there will be none with smaller value to the left of position p and none with larger value to the right. Thus the original sorting problem is transformed into the two disjoint subproblems of sorting the first $p - 1$ and the last $n - p$ components of the resulting vector. The same technique is then applied recursively to each of these subproblems. The method is likely to sort the vector x in $O(n \log n)$ operations, but may require as many as $O(n^2)$ operations in extreme cases.

4.2 Heapsort

The heapsort method is due to J. W. J. Williams (Algorithm 232, Communications of the ACM **7** (1964), 347-348). Subroutine SORT_heapsort_build is a partial amalgamation of Williams' Algol procedures *setheap* and *inheap* while SORT_heapsort_smallest is based upon his procedures *outheap* and *swopheap*.

The elements of the set $\{x_1, x_2, \dots, x_n\}$ are first allocated to the nodes of a heap. A heap is a binary tree in which the element at each parent node has a numerical value as small as or smaller than the elements at its two children. The smallest value is thus placed at the root of the tree. This value is now removed from the heap and a subset of the remaining elements interchanged until a new, smaller, heap is constructed. The smallest value of the new heap is now at the root and may be removed as described above. The elements of the initial set may thus be arranged in order of increasing size, the i -th largest element of the array being found in the i -th sweep of the method. The method is guaranteed to sort all n numbers in $O(n \log n)$ operations.

All use is subject to licence. See <http://galahad.rl.ac.uk/galahad-www/cou.html>.
For any commercial application, a separate license must be signed.

5 EXAMPLE OF USE

The following example is a somewhat unnatural sequence of operations, but illustrates the use of the SORT tools. It uses the data vector

$$x = \{x_1, x_2, \dots, x_{20}\} = \{-5, -7, 2, 9, 0, -3, 3, 5, -2, -6, 8, 7, -1, -8, 10, -4, 6, -9, 1, 4\}.$$

Suppose now that we wish to perform the following successful operations:

1. sort the components of x in ascending order and compute the associated inverse permutation,
2. apply this permutation to the resulting vector (in order to recover its original ordering),
3. restore the permutation to the identity by sorting its components in ascending order,
4. find the 12 smallest components of x and the associated inverse permutation,
5. inverse this permutation (which yields the permutation used to sort the 12 smallest components),
6. apply to the permuted x the inverse of the this latest permutation (thus recovering its original ordering again).

Then we may use the following code

```

PROGRAM GALAHAD_SORT_EXAMPLE
USE GALAHAD_SORT_double           ! double precision version
IMPLICIT NONE
INTEGER, PARAMETER :: wp = KIND( 1.0D+0 ) ! set precision
INTEGER, PARAMETER :: n = 20

Apply the resulting permutation to x

The final vector is

-5.0	-7.0	2.0	9.0	0.0	-3.0	3.0	5.0	-2.0	-6.0
8.0	7.0	-1.0	-8.0	10.0	-4.0	6.0	-9.0	1.0	4.0
